Generalised no-broadcasting for process theories

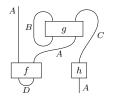

Bob Coecke and Aleks Kissinger

This result appears in the forthcoming textbook [4] as well as in the book chapter [3].

The (universal) no-broadcasting theorem states that there exists no quantum process Δ from 1 system to 2, such that, for any quantum state ρ , discarding (i.e. tracing out) either system of $\Delta(\rho)$ yields ρ itself [2]. This theorem has been generalised within the context of generalised probabilistic theories in [1]. Here, we generalise it within the context of process theories. For more background on the process theory framework and other details we refer to [3].

1 Background

A string diagram consists of a collection of boxes which can have some inputs, depicted as wires coming in the bottom of a box, and some outputs, depicted wires coming out of the top. We allow arbitrary connections between boxes, including those from inputs to inputs, and outputs to outputs:

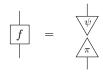

String diagrams can furthermore be reflected vertically:

$$\begin{bmatrix} B \\ f \\ A \end{bmatrix} \xrightarrow{\dagger} \begin{bmatrix} f \\ f \\ B \end{bmatrix}$$

indicating the *adjoint* of the diagram. A process theory is an interpretation of all diagrams made up of a fixed collection of boxes (as well as their adjoints) and wires. A two-system state ψ is \otimes -separable if there exist states ψ_1 and ψ_2 such that:

and that a process f is \circ -separable if there are effect π and state ψ such that:

Suppose we have a \circ -non-separable process, and imagine that it has some internal structure, say a collection of tubes connecting some inputs to outputs:

If we now compose this process with its vertical reflection, then these internal connections match up:

so one expects the resulting process also to be \circ -non-separable. That is:

$$\left(\exists \psi, \phi : \boxed{f}_{\downarrow} = \underbrace{\downarrow}_{\psi}_{\downarrow} \right) \Longleftrightarrow \left(\exists \psi', \phi' : \boxed{f}_{\downarrow} = \underbrace{\downarrow}_{\psi'}_{\psi} \right)$$

We call this rule *dagger-connectedness*.

Example 1.1. For linear maps, o-separable means rank-1. So, *dagger-connectedness* follows from the

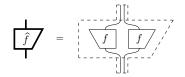

fact that the rank of $f^{\dagger} \circ f$ is the same as the rank of *Proof.* Writing ρ in the form (1): f. However, this fails for relations. Consider:

$$R := \{(0,0), (0,1), (1,1)\} \subseteq \{0,1\} \times \{0,1\}$$

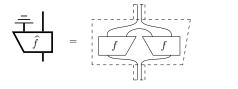

Clearly R is \circ -non-separable, but $R^{\dagger} \circ R$ is \circ separable.

By a *quantum system* we mean a wire of the form:

A *pure quantum process* is of the form:

while a general quantum process is of the form:

where we used *discarding*:

$\mathbf{2}$ Main result

Consider a process theory that admits string diagrams and obeys dagger-connectedness.

Proposition 2.1. If a *reduced state* of ρ (i.e. a state arising from discarding some part of ρ) is pure:

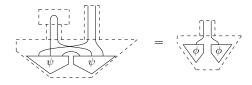

$$\begin{array}{c} \overline{-} \\ \hline \\ \rho \end{array} = \begin{array}{c} 0 \\ \phi \end{array}$$
 (2)

then ρ \otimes -separates as follows:

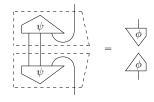

$$\begin{array}{c} \begin{array}{c} & \\ & \\ & \\ \end{array} \end{array} = \begin{array}{c} \\ & \\ & \\ \\ & \\ \end{array} \end{array} \begin{array}{c} \\ \\ \\ \\ \\ \end{array} \end{array} \begin{array}{c} \\ \\ \\ \\ \\ \end{array} \end{array}$$
 (3)

and substituting this into (2) we obtain:

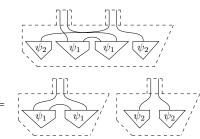

Deforming this equation we get:

Then, by dagger-connectedness there exist ψ_1, ψ_2 s.t: (1)

Plugging in to (3) yields the required separation:

Then, substituting into (2) we can conclude that $\hat{\psi}_2 = \hat{\phi}$.

Proposition 2.2. If a *reduced process* is pure:

$$\begin{array}{c} \underline{-} \\ \underline{-} \\ \underline{-} \\ \underline{-} \\ \underline{-} \end{array} = \begin{array}{c} \underline{-} \\ \underline{-} \\ \underline{-} \\ \underline{-} \end{array}$$
 (4)

then it \otimes -separates as follows:

Proof. Bend the wire in (4):

$$\frac{\overline{-}}{\widehat{f}} = \widehat{f}$$

By Proposition 2.1 it separates as follows:

$$\begin{array}{c} & \mathbf{I} \\ & \mathbf{\Phi} \end{array} \end{array} = \begin{array}{c} & \mathbf{I} \\ & \boldsymbol{\rho} \end{array} \begin{array}{c} & \mathbf{f} \\ & \hat{f} \end{array} \end{array}$$

Unbend the wire and we're done.

Theorem 2.3. If there is a quantum broadcasting process, that is, a quantum process Δ s.t.:

then every plain wire o-separates, and consequently, every process o-separates. Consequently, non-trivial process theories cannot have such a process.

Proof. By equation (61) the reduced state of Δ is pure, so by Proposition 2.2 we have:

$$\begin{bmatrix} \Delta \\ 1 \end{bmatrix} = \begin{bmatrix} P \\ P \\ 1 \end{bmatrix}$$
(7)

for some state ρ . Hence it follows that:

3 Discussion

(5)

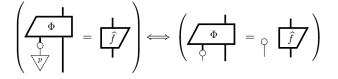

Clearly the crux of this result is the influence of dagger-connectedness on the 'doubled' form of quantum processes.

In fact, we know that dagger-connectedness is strictly stronger than no-broadcasting since the process theory obtained from 'doubling' relations also satisfies no-broadcasting [5], yet relations themselves fail dagger-connectedness, as we saw in Example 1.1.

Furthermore, with the help of so-called 'spiders' for capturing the interaction with classical data, many other results arise from dagger-connectedness [4]. Notable examples are the existence of entangled states:

□ and the fact that pure process cannot arise from nontrivial convex mixtures of processes:
